ABSTRACT

[00125]   An object framework can provide unique and uniform methods for explicit and precise object identification. The object framework features a virtual object space providing access to multiple objects, each object having a set of functionality and being identifiable by a unique identifier provided by the virtual object space. A visualization framework visualizes objects independent of an application implementing an object. Each object is visualized using the object's unique identifier and according to the object's corresponding set of functionality.
